THE PROBLEM

Agent fleets earn and spend USDC around the clock — with no bank

Fleets are companies now

Businesses employ fleets of AI agents that earn income, pay for APIs and services, and settle jobs in USDC — continuously, autonomously.

Wallets ≠ a bank

Explorers show raw hashes. There are no per-agent accounts, no statements, no month-end books, no categorized P&L.

Finance teams are blind

"Which agent made money last month? What did we spend on compute? Where is the export for our accountant?" — today, no answer exists.

"Your accountant cannot file this."

No one closes the books for agent fleets

Who	What they do	Books for agent fleets?
Catena Labs (\$30M, OCC filing)	Banking & governance for agents — humans control agent money	No
Circle Agent Stack (May 2026)	Agent wallets, marketplace, nanopayments — “exclusively payment mechanics”	No
Fireblocks + TRES · MoonPay + Entendre	Crypto accounting — for human companies	No
Basis (\$1.15B) · Pilot AI Bookkeeper	Accounting agents for human firms, off-chain	No

Adversarially re-verified against the live landscape (Cambrian Q1-26 map, arXiv agent-finance survey, vendor docs). **Everyone stops at wallets, payments, or policy. Nobody produces the books.**

On Arc, the chain itself is a complete bank record

21%

of USDC-moving transactions emit NO ERC-20 log — invisible to every normal indexer. We measured it on live Arc testnet.

EIP-7708 (Arc-only)

Every native USDC movement emits a Transfer log from the system emitter 0xffff...fffe — statements are gapless, derived purely from chain data.

On Ethereum: impossible

Native transfers emit no logs. A statement built from events silently misses 1 in 5 movements.

Proven in our repo

2,000 live blocks: 9,911 system logs vs 6,946 ERC-20 logs; dual-log dedupe + gas-from-receipts rules codified and tested (docs/spike-eip7708.md).

This product is only fully buildable on Arc.

THE PRODUCT

A real bank account for every agent — and books that close themselves

Per-agent accounts

Circle dev-controlled SCA wallets; Gas Station pays all gas — agents never touch a gas token.

Gapless statements

The EIP-7708 indexer captures every movement; amounts quantized to bank-grade 6 decimals.

EVERY NUMBER IS CHAIN-DERIVED

The AI only ever fills the category column and writes the summary. The amounts, balances and totals come from Arc — deterministic, auditable, reproducible.

AI bookkeeper (gated)

Categorizes every line with confidence — behind a golden-set accuracy gate; low confidence escalates, never guesses.

Month-end close

Per-agent P&L, fleet statement, AI-written summary, CSV/QuickBooks export, reconciled against Circle's API by refld.

Two vendors, same verdicts:

DeepSeek 12/12 · GPT-4o-mini 11/12 on the committed golden set — the harness determines the books, not the model.

The banker is an agent too

Its own wallet & identity

Bailey holds a Circle SCA wallet and an on-chain ERC-8004 identity — registered live on Arc testnet.

Employed by the fleet

The month-end close is a paid job: the fleet funds an ERC-8183 escrow, Bailey delivers the statement, PaymentReleased pays Bailey.

Real decision gates

Holds the close while escrows are pending · refuses sign-off if refld reconciliation fails · escalates low-confidence lines. Every decision lands in a visible journal.

In its own books

Bailey's fee appears — correctly categorized — in the very statement it just produced. Same pipeline, zero special-casing.

Bailey never moves fleet funds — it observes, reports, delivers, and gets paid. Bailey is software, not a bank or custodian.

All of this is running on Arc testnet today

6

Circle SCA wallets live — 5 agents + Bailey — each with an on-chain ERC-8004 identity; every tx gas-sponsored by Gas Station

17

real USDC movements indexed through the EIP-7708 rule and rendered into per-agent statements with running balances + CSV

100.0000000

fleet books balance to the micro-cent: five 20-USDC faucet fundings; every internal payment cancels exactly

12/12

golden-set eval gate passed (DeepSeek; GPT-4o-mini 11/12) before the model was allowed to touch the ledger

0

escalations once Circle refId context was joined — and 100% honest escalation without it: the bookkeeper never guesses

21%

of USDC txs invisible to ERC-20 indexers — measured live, captured completely by Bailey's system-emitter rule

From chain noise to closed books

Correctness rules, validated live: index ONE emitter (every ERC-20 transfer emits two logs) · fees emit no Transfer log — derive gas from receipts · quantize to 6 decimals · order by (block, logIndex), zero reorgs · escrow amounts are net-of-fee

Deep use of the right core products

Arc testnet — the L1 everything runs on

Native USDC + EURC — one asset, two views — handled correctly

Circle Wallets — dev-controlled SCA — the deliberate custody model for a business-owned fleet

Gas Station / Paymaster — agents never touch a gas token

List-Transactions refld — off-chain context reconciled to on-chain truth

ERC-8004 + ERC-8183 — Arc's agentic stack: identities + job escrow (income rail + Bailey's pay)

Circle CLI · Skills · MCP — Agent Stack tooling in the dev loop

CCTP — cross-chain mints land as categorized "funding" lines

Roadmap name-drops (honestly scoped): StableFX (live on testnet — DeFi-track) · Nanopayments/x402 billing · Circle Contracts webhooks as the production indexer.

WHERE THIS GOES

The books are the platform: credit, yield, and spend rails

Bailey Credit

A lender needs to trust the borrower's books. Agent fleets have none — except Bailey's: gapless, categorized, eval-gated. The books ARE the credit bureau.

Underwritten from live P&L: income stability, margins, refund rate. At Arc mainnet, capital routes to Aave V4 on Arc — deployment proposal live since June 2026.

Treasury yield (USYC)

Individual agents can never reach institutional yield (\$100k min, institutions-only). Bailey pools the fleet's idle balances into a treasury that can.

USYC — Circle's \$1.6B tokenized money-market fund — is live on Arc testnet; Bailey sweeps idle balances and books yield as categorized income.

Spend rails settle in

Agents will "swipe" everywhere: x402/Nanopayments today (live on Arc testnet), Visa Intelligent Commerce & Mastercard Agent Pay tomorrow.

Bailey is the account every swipe settles INTO — receipts reconciled against settlement like a card statement. Visa is Arc's lead design partner and planned validator.

Every claim above is verified: real contracts, real governance proposals, real partnerships — July 2026.

Machine-payable banking, sold to finance teams

Per-agent-seat SaaS — the finance team buys Bailey like they buy payroll — per agent, per month

Machine-payable per-close billing — the fleet pays Bailey in USDC for every close — metered, on-chain, already working

FX conversion bps + premium exports — StableFX treasury policies · QuickBooks/Xero integrations (roadmap)

Buyer: the finance team of any company running an agent fleet. The stack: spend control (pre-tx policy) → trust (who to transact with) → BAILEY: accounts + books (what happened to the money) — with Catena and Circle as complementary rails beneath.

WHY WE WIN

- Only fully buildable on Arc (EIP-7708 — measured)
- The bookkeeper is a market participant — the first bank whose banker appears in its own books
- Correctness as moat: eval gates, decision journals, micro-cent reconciliation
- Whitespace verified: nobody closes the books for agent fleets

settlement

Your agents do the business.
Bailey keeps the books.

Bailey — after George Bailey of “It’s a Wonderful Life”: the banker who knew where every dollar lived.

Bailey is software, not a bank or custodian — funds never leave your fleet’s Circle wallets.
